

- a) The file server stores all files and it can be operated from any workstation. It contains information and a lot of data, it needs a lot of ram and heaps of hard disk space. The network will need a lot of cable to use it.
- b) As the database increases in size more data is going to lost due the distance that it has travelled. The file server may not be able to cope with so much data coming in and out and also not enough hard disk space. Also some computers will slow the rest of the network down causing some data to be lost.
