b)ii) "Write enter width + readlh"
it can't work if a width isn't entered, to rectify this, a width should be entertened in the system, but not as a variable

c) $\frac{1}{2} \times b \times h$, needs to be told that the bottom length needs to be $\frac{1}{2}$ d in order for a reading to be gatheed, well a correct one anyway. if it's $\frac{1}{2}$ a side, it wont give the correct area.

d) using the object-orientated Paradigm to Sort the baggage onto chutes, object would be Sorted by class + flight time arrival, in this way bags would be Sorted Correctly, in order of 1st down to 3rd Class + on flight arrival. it will then asses how many chutes

will be needed to combat the workload in a fast efficient manner
